

Order Reassignment Recommendations — Planner View

What changed, why, and what it means for the business

The situation

93 open orders could not be fully shipped from their assigned warehouse because that warehouse didn't have enough stock on hand. Left as-is, only 14% of these orders would ship on time — the rest would be late, partial, or cancelled.

What we recommend

Move 38 of these orders to a different warehouse that does have the stock. This raises on-time fulfillment from 14% to 53%, and captures \$447,822 in order value after accounting for the extra delivery cost of shipping from a farther warehouse — more than double what leaving orders as-is would recover.

A few examples

Order	Move from Warehouse	Move to Warehouse	Order Value
U108966275	5620	5490	\$65,673
U108955078	5410	5490	\$21,310
U108963192	5620	5420	\$18,724
U108971149	5420	5641	\$16,985
U108948387	5410	5385	\$10,721

These are the highest-value moves recommended — each one is a case where a nearby warehouse has stock the assigned one doesn't, and the extra delivery cost is worth paying to capture the order.

What's not recommended, and why

44 of the 93 orders are left unfulfilled by this recommendation. In every one of these cases, no warehouse in the network had enough stock to cover the order — moving them wouldn't have helped, it would just shift the shortage somewhere else. These are flagged as needing a supply-side fix (more stock, a supplier order, or a customer conversation about timing), not a shipping fix.

Why not just move every order to wherever has stock?

We tested that too (a simple "always divert" rule) — it does get more orders shipped (89% instead of 53%), but it nearly doubles total delivery cost in the process, and ends up capturing less value overall (\$412,060 vs. \$447,822). The recommendation above is the one that gets the most value out of the network, not just the most orders shipped.

Confidence in this recommendation

This was checked against a mathematically exact solver (guaranteed best possible answer for this data) and against five other computational methods, including two experimental "quantum-inspired" approaches. All methods point the same direction; the recommendation above is the best-performing one found.
